Aim
We aimed to assess diagnostic accuracy of ESPEN’s Diagnostic Criteria for malnutrition (EDC), as compared to the Patient-Generated Subjective Global Assessment (PG-SGA) in selected clinical populations.

Conclusion
In COPD, rectum-colon cancer, and orthopedic patients, diagnostic accuracy of EDC as compared to the PG-SGA is low, especially sensitivity and negative predictive value. Consequently, using EDC in these populations is likely to result in underrecognition of malnutrition, which may hinder timely and adequate treatment of malnutrition.

Methods
In two hospitals, in 174 patients, malnutrition was assessed by EDC and PG-SGA. According to EDC, malnutrition was defined as having at least one of the following criteria:
• BMI <18.5 kg/m²
• Combination of unintentional weight loss (>10% of habitual weight indefinite of time, or >5% over 3 months) and low BMI (<20 or <22 kg/m² in subjects younger and older than 70 yrs, respectively) and/or a low fat-free mass index (FFMI) (<15 [female] and <17 kg/m² [male]).

As reference, malnutrition was defined as PG-SGA Stage B (moderately/suspected malnutrition) or Stage C (severely malnourished). Diagnostic accuracy was assessed by sensitivity, specificity, positive and negative predictive value, and the receiver operating characteristic (ROC) curve.
